MODELS
OF CYCLICAL
GROWTH

Novosibirsk
2003

Ryzhenkov A. V. Models of Cyclical Growth. – Novosibirsk: IEIE SB RAS, 2003. – 240 p.

Regularities of big cycles of conjuncture and sustainable development belong to the most important ones for the theory and strategy of economic development. This monograph penetrates these regularities in depth on rich statistical data with a help of modern mathematics (the theory of non-linear differential equation, extended Kalman filter) and computer technique. By enhancing mathematical and instrumental methods of the economic theory and system dynamics, this monograph may help in elaborating a long-term strategy of Russia's development allowing for higher growth rates of the domestic economy than economic growth rates in the USA and other industrialised countries.

Investment and foreign trade planners, teachers of economic theory and mathematical modelling, researchers of capitalist economy, students and post-graduate students of economic theory and mathematics at higher schools will benefit from reading this advanced book.

MODELS OF CYCLICAL GROWTH

Alexander V. Ryzhenkov

Abstract

The Dutch artist Vincent van Gogh once expressed a fine thought: “I consider making studies like sowing and making pictures like reaping... It is easier to proceed from drawing to painting, than, conversely, to make pictures without drawing the necessary studies...” The same approach is typical for the system dynamics modelling. Rephrasing V. Van Gogh, we may say that a system of differential equations is the skeleton, statistics are the muscles of the sturdy system dynamics model.

This book defines a deterministic form of a *hypothetical Law of capital accumulation* (HL) as a system of non-linear ordinary differential equations based on real data. The state variables are the relative wage, employment ratio, unit gross rent, unit depletion and degradation of the natural capital, man-made capital-output ratio, natural capital-output ratio and indicated natural capital-output ratio. An operational policy within the scope of the existing and potentially feasible regulatory institutions for achieving sustainable development is also included. Complexity results from the high degree of interrelatedness of these structural elements, non-linearity of the functional forms and informational delays in this model. The fundamental equation of neo-classical growth is a special case of the more general dynamic regularity, presented as a direct consequence of the HL.

The present author makes use of four idealisations of an actual economic development of industrialised capitalist economy that could be considered as four subsequent steps for the derivation of the Law of capital accumulation. This Law subsumes all of them. Its rough-

ness corresponds to the real systems' property of relative structural stability.

A *first order* idealisation is a steady state growth that is locally or even globally stable. Accordingly, technical progress and growth of labour force tend to result in steady economic growth while long waves represent important fluctuations about this trend. The Kaldor's stylised facts are valid for steady state growth path still it is a too remote image of reality where all equilibrium states are locally unstable and cannot maintain themselves for any significant length of time.

A *second order* idealisation is mathematically a limit cycle that results from a locally unstable stationary state. Since no linear system can lead to a limit cycle, a dynamic economic model must be essentially non-linear. A limit cycle can be generated via Andronov – Hopf bifurcation if a steady state loses its stability when a control parameter passes a critical magnitude. This is not the only possible mechanism for manifestation of closed orbits. They may go around a neutral steady state like in the structurally unstable Goodwin model with the two phase variables (relative wage and employment ratio). Alternatively, they may exist in a system that cannot be linearised at a locally unstable stationary state and at points with the maximal or minimal employment ratios at all. This book argues that the latter case of the substantially non-linear dynamic system is the mostly realistic since it takes into account incompatibility of full employment with the institutional structure of capitalism.

The Kaldor's stylised facts are true on average for a limit cycle. This property contradicts the Marx Law of the tendency of the general profit rate to fall that has been supported by US official statistics for 1948–2000. The society accumulates the produced capital, however its activity brings about the excessive depletion and degradation of the natural environment that is detrimental for the unbiased general profit rate and net rent rate over the long term. Accumulation of produced assets and accumulation of developed natural assets are necessary for strongly sustainable development.

A *third order* idealisation is a transition motion to a limit cycle in a more structurally stable dynamic system. As proved, such a system cannot be linearised in neighbourhood of a locally unstable stationary state. The Law of the tendency of the general profit rate to fall

operates on the transient to a periodic attractor for centuries. A shortcoming of the third order idealisation is that a transient regime is too regular and repetitive. It leads to a periodic motion where the general profit rate is constant on the average.

It has been shown that the real US economy exhibits a long wave as a dominant quasi-cycle. A long wave is not a mere fluctuation superimposed on steady, balanced growth; rather, a long wave is a part of the very process of non-equilibrium growth in the capitalist economy. A *fourth order* idealisation is a long wave as a stochastic attractor and quasi-periodic trend with a quasi-period of about 29–33 years in the US economy after the Second World War.

The stochastic model that generates this long wave has been written in a canonical state space form. Setting a probabilistic form of the HL, it reflects additionally discrepancies (including effects of shorter quasi-cycles) in the dynamic equations and in measurement equations. An application of the extended Kalman filtering to the US macroeconomic data has identified unobservable components of this Law. The retrospective statistical analysis (1958–1991), univariate sensitivity analysis (1991–2034) and forecasting (1991–2107) have supported the analytical treatment. An exploratory and a normative scenarios have contrasted the strongly sustainable development to an unsustainable evolution.

The present downturn in the long wave is to be viewed not only as regularly recurrent phase of the long wave. Its additional pains are, likely, characteristic of childbirth of the natural capitalism. The ‘old’ industrial capitalism is thus experiencing the dialectical negation, or creative destruction. The system dynamics approach could be helpful for shortening and lessening disorder and distress of this major global transformation. The conscious element of the Law plays a decisive role in providing better governance of the ecological-economic reproduction on the increasing scale when ecology remains one of the major political issues.

Acknowledgement

This monograph is based on the author’s research over a number of years. It is a baby of a cultural cross-over. Parts of this research

have been carried out at the Institute of Economics and Industrial Engineering (IEIE) in Novosibirsk (Russia), Mannheim University (Germany), Worcester Polytechnic Institute (WPI) in the USA, Gakushuin University (GU) in Tokyo (Japan).

Professor K. K. Valtukh and other colleagues have facilitated the work done in Novosibirsk. Professor R.M. Goodwin's letters in 1993–1994 have lent new wings to this research endeavour.

The author would like to express a special gratitude to Professor Peter Milling for his lessons on the system dynamics at the Mannheim University in 1992–1993, 1997–1998 and 2003. The valuable research assistance of Dr. I. Jäger in Germany in 1992–1994 is also appreciated.

Professor M. Myrtveit (ModellData AS in Norway) and Professor L. Vavik (Stord/Haugesund College, Norway) have provided the author with the *Powersim* learning environment in 1995. That has enabled a lot of exciting computer simulations only partially presented in this book.

The flight simulator and papers on long waves by Professor J. Sterman from the MIT (Boston, the USA) awoke the author's latent interest in the field of system dynamics more than 15 years ago. The insightful comments by Professor Kh. Saeed, Professor M. Radzicki and other American colleagues at the WPI have facilitated the author's research in 1999.

At the Gakushuin University (GU) in 2000–2001, the author has learnt much on economy, technology and society from his host Professor Michiya Morita. Dr. R. Eberlein (Ventana Systems, Inc. in the USA) has been very helpful by his professional guidance on the software Vensim in 2001.

Alexander von Humboldt Foundation has provided a financial support in Germany and donated the computer facilities for the research at the home Institute. The World Society Foundation and AVINA Foundation have financed the stay at the WPI. The research project in Japan has been due to a financial and organisational support by the GU International Exchange Centre. The contribution of these organisations, as well as the support by Russian Academy of Sciences, is deeply appreciated.

CONTENTS

<i>Introduction</i>	6
CHAPTER 1. A simple model of cyclical growth and capital accumulation with induced technical progress	27
1.1. Premises of a simple model of cyclical growth	27
1.2. The model equations	30
1.3. An intensive form of the simple model	35
1.4. A stationary state in a phase space	40
1.5. Local stability of the stationary state	43
1.6. An exponential trend	49
1.7. A competitive-co-operative structure of capital accumulation	53
<i>Conclusion</i>	57
CHAPTER 2. A model of the law of the tendency of the general profit rate to fall	61
2.1. A limit cycle of uneven growth	61
2.2. Anticipation in the self-regulation of capitalist economy ...	66
2.3. Profitability, productivity and scale effect	69
2.4. Economic long-waves in the USA in 1948–2000	85
<i>Conclusion</i>	94
CHAPTER 3. Models of capitalist development constrained by natural resources	97
3.1. Incorporating natural capital in the simple model of long waves	99
3.2. An example of ecological and economic catastrophe (aggravated instability)	107
3.3. An environmental policy and resource rent in a modified model	111
3.4. The scale effect and theoretical outgrowth of a law of capital accumulation	114
3.5. Computer simulations of sustainable cyclical development	118
<i>Conclusion</i>	120
CHAPTER 4. Generalising the fundamental equation of the neo-classical theory of economic growth	123
4.1. Basic elements of Solow's neo-classical model	123
4.2. Possible trajectories of neo-classical growth	125

4.3. A generalisation of the fundamental equation	135
<i>Conclusion</i>	139

CHAPTER 5. A hypothetical law of capital accumulation	142
5.1. Equations of a modified deterministic model	142
5.2. A hypothetical law of capital accumulation in determi- nistic and probabilistic forms	146
5.3. A simplified version of an extended Kalman filter	149
5.4. An impossibility theorem of whiteness of innovations	153
<i>Conclusion</i>	156
CHAPTER 6. Operation of the hypothetical law of capital ac- cumulation in the American economy in 1958–1991	158
6.1. A historical fit of a retrospective forecast	159
6.2. Properties of smoothed series of quasi-cyclical growth ...	173
<i>Conclusion</i>	177
CHAPTER 7. Exploratory and normative forecasts of the USA economic development in 1991–2107	179
7.1. An exploratory forecast: decelerating capital accumu- lation	179
7.2. A normative scenario for 1991–2107: extending natural capital	186
<i>Conclusion</i> ..	189
